# From text to formal specification: a too big step

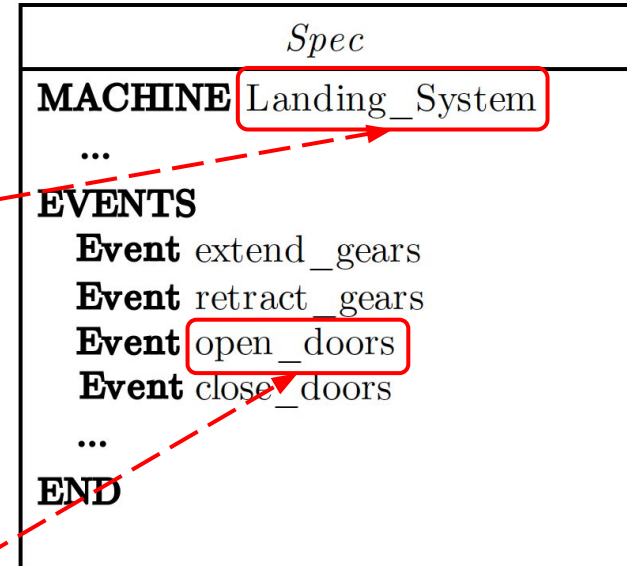

Fig. 1. Landing set

The system is controlled digitally in nominal mode and analogically in emergency mode. In this case study, we do not consider the emergency mode. However, in order to allow the pilot to activate the emergency command, the system has to elaborate health parameters for all the equipments involved in the landing gear function. This health monitoring part is in the scope of the case study.

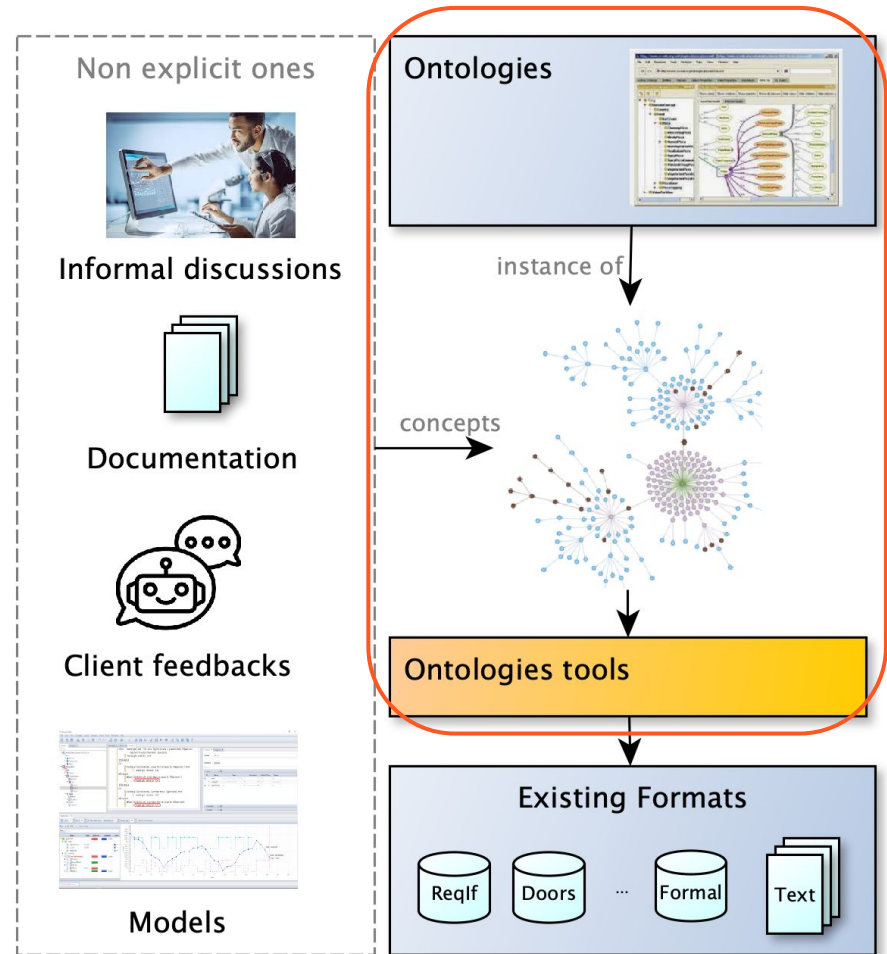

In nominal mode, the landing sequence is: open the doors of the landing gear boxes, extend the landing gears and close the doors. This sequence is illustrated

# IEEE/SWEBOK/ISO definition of a Requirement

## “A 1.1 Definition of a Software Requirement

At its most basic, a software requirement is a property that must be exhibited by something in order to solve some problem in the real world. It may aim to automate part of a task for someone to support the business processes of an organization, to correct shortcomings of existing software, or to control a device—to name just a few of the many problems for which software solutions are possible. The ways in which users, business processes, and devices function are typically complex. By extension, therefore, the requirements on particular software are typically a complex combination from various people at different levels of an organization, and who are in one way or another involved or connected with this feature from the environment in which the software will operate.

”

[http://swebokwiki.org/Chapter\\_1:\\_Software\\_Requirements](http://swebokwiki.org/Chapter_1:_Software_Requirements)

# Context (universe of discourse)

“a **project** to develop a **system**, in a certain **environment**, to satisfy a set of **goals**”

# (our) General definition of a Requirement

“A requirement is a (relevant) **statement** about a **project**, **environment**, **goals** or **system property**”

# Elements of graphical representation

A requirement can be **Atomic** or **Composite**

The **type** of a requirement is the notation in which it is expressed (English, SysML, Eiffel, ...)

“The LGS has three components.”

## Some basic concepts

**Property:** boolean predicate (on a project, system or environment)

**Statement:** human-readable expression of a property

# Kind of requirements (overview)

# Kind of requirements (common to all PEGS)

- Component
- Responsibility
  - *Role*
- Limit

# Kind of requirements (Goals)

- Goal
  - *Obstacle*

# Kind of requirements (Projects)

- Task
- Product

# Kind of requirements (System)

- Behaviour
  - *Functional*
  - *Non-functional*
  - *Example*

# Kind of requirements (Environment)

- Constraint
  - *Business rule*
  - *Physical rule*
  - *Engineering decision*
- Assumption
- Effect
- Invariant

# Kind of requirements (Document description)

- Silence
- Noise
  - *Hint*
- Meta-requirement
  - *Justification*

# Classification (overview)

# Categories of requirements (derived)

- **Actor** (from Component)
- **Justification** (from Meta)
- **Role** (from Responsibility)
- **Obstacle** (from Goal)
- **Hint** (from Noise)
- **Obligation** (from Constraint)
- **Functional** (from Behavior)
- **Non-Functional** (from Behavior)
- **Example** (from Behavior)

# Categories of relations

# Relations between requirements

- Disjoins ( $X \parallel Y$ )
- Belongs ( $X \subseteq Y$ )
- Repeats ( $X \Leftrightarrow Y$ )
- Contradicts ( $X \oplus Y$ )
- Extends ( $X > Y$ )
- Excepts ( $X \setminus Y$ )
- Constrains ( $X \triangleright Y$ )
- Characterizes ( $X \rightarrow Y$ )

# X and Y are unrelated

$X \parallel Y$

“The system is composed of three components.”

“The car should be as economic in fuel consumption as possible.”

# Y is a sub-requirement of X

$$Y \subseteq X$$

$Y \xrightarrow{<<BELONGS>>} X$

“4.3. System Externals”

“A customer is any user of the system that has not identified himself as an SBE employee.”

# X specifies the same property as Y

$$X \Leftrightarrow Y$$

“The system is composed of three components.”

“Here are the descriptions of the three parts of the system:”

# X specifies a property in a way not compatible with Y

 $X \oplus Y$ 

$X \xleftrightarrow{\text{<CONTRADICTS>}} Y$

“The system has no interaction with human.”

“The user should login interactively with the system.”

$X > Y$

X assumes Y and specifies a property not specified by Y

“The online product ordering should allow direct access to the confirmation page.”

“The system shall allow for online product ordering by either the customer or the sales agent.”

X \\ Y

X changes or removes, for a specified case,  
a property specified by Y

“In case of emergency braking,  
the system should prevent the  
wheels from freezing.”

“The wheel can be frozen by  
braking.”

$X$  specifies a constraint on a property specified by  $X$   $X \triangleright Y$

“The user is registered.”

“In order to get personalized or restricted information, place orders or do other specialized transactions a user must login so that that the system can determine his access level.”

# X is a meta-requirement involving Y

$$X \rightarrow Y$$

“The following requirement is optional:”

“The car should looks like a Ferrari.”

## Object-Oriented Requirements: a Unified Framework for Specifications, Scenarios and Tests

**ABSTRACT** A paradox of requirements specifications as dominantly practiced in the industry is that they often claim to be object-oriented (OO) but largely rely on procedural (non-OO) techniques. Use cases and user stories describe functional flows, not object types. To gain the benefits provided by object technology (such as extensibility, reusability, and reliability), requirements should instead take advantage of the same data abstraction concepts – classes, inheritance, information hiding – as OO design and OO programs.

Many people find use cases and user stories appealing because of the simplicity and practicality of the concepts. Can we reconcile requirements with object-oriented principles and get the best of both worlds?

This article proposes a unified framework. It shows that the concept of class is general enough to describe not only “object” in a narrow sense but also scenarios such as use cases and user stories and other important artifacts such as test cases and oracles.

Having a single framework opens the way to requirements that enjoy the benefits of both approaches: like use cases and user-stories, they reflect the practical views of stakeholders; like object-oriented requirements, they lend themselves to evolution and reuse.

**KEYWORDS** Software requirements, use cases, scenarios, scenario-based testing, object-oriented requirements, specifications

### 1. Introduction

A good software system is an effective solution to a well-understood problem. As software engineering has progressed, it has become increasingly clear that achieving software quality involves achieving quality on both the solution side and the problem side: together with excellent design, implementation and project management techniques, a successful project requires an excellent description of the problem, known as the **requirements** of the system.

While a considerable body of knowledge exists about requirements engineering, the discipline as practiced in industry has not yet experienced the considerable progress that *object-oriented* (OO) concepts, methods, languages and tools have brought to solution-side tasks. The purpose of this article is to help advance the state of the art in requirements engineering through the application of OO ideas, and to show that this approach subsumes other widely applied techniques such as use cases and user stories. The research questions we tackle in this paper are (i) how to specify OO requirements? (ii) how to unify them with scenarios?

The *modeling power* of object technology has played a large part in its success for design and implementation, and can be even more useful for requirements. It comes in particular from the OO decision to define the architecture of systems on the basis of object types connected by well-defined relations (“client” and
